1 Best Prediction

1.1 Under 0-1 Loss (10 pts)

Suppose the world generates a single observation $x \sim \text{multinomial}(\theta)$, where the parameter vector $\theta = (\theta_1, \dots, \theta_k)$ with $\theta_i \geq 0$ and $\sum_{i=1}^k \theta_i = 1$. Note $x \in \{1, \dots, k\}$. You know θ and want to predict x . Call your prediction \hat{x} . What is your expected 0-1 loss:

$$\mathbb{E}[\mathbb{1}_{\hat{x} \neq x}]$$

using the following two prediction strategies respectively? Prove your answer.

1. Strategy 1: $\hat{x} \in \arg \max_x \theta_x$, the outcome with the highest probability.
2. Strategy 2: You mimic the world by generating a prediction $\hat{x} \sim \text{multinomial}(\theta)$. (Hint: your randomness and the world's randomness are independent)

Solution: denote the order statistic of θ as $\theta_{(1)}, \dots, \theta_{(k)}$, in which $\theta_{(k)}$ is the largest.

For strategy 1, we have

$$\begin{aligned} \mathbb{E}(\mathbb{1}_{\hat{x} \neq x}) &= \mathbb{P}(\hat{x} \neq x) \\ &= 1 - \mathbb{P}(\hat{x} = x) \\ &= 1 - \theta_{(k)} \end{aligned} \tag{1}$$

For strategy 2, we have

$$\begin{aligned} \mathbb{E}(\mathbb{1}_{\hat{x} \neq x}) &= \mathbb{P}(\hat{x} \neq x) \\ &= 1 - \mathbb{P}(\hat{x} = x) \\ &= 1 - \sum_{i=1}^k \theta_i^2 \end{aligned} \tag{2}$$

1.2 Under Different Misclassification Losses (6 pts)

Like in the previous question, the world generates a single observation $x \sim \text{multinomial}(\theta)$. Let $c_{ij} \geq 0$ denote the loss you incur, if $x = i$ but you predict $\hat{x} = j$, for $i, j \in \{1, \dots, k\}$. $c_{ii} = 0$ for all i . This is a way to generalize different costs of false positives vs false negatives from binary classification to multi-class classification. You want to minimize your expected loss:

$$\mathbb{E}[c_{x\hat{x}}].$$

Derive your optimal prediction \hat{x} .

Solution: for simplicity, denote $\mathbb{P}(\hat{x} = j), j = 1, \dots, k$ as \hat{p}_j . Then the expected loss can be calculated as

$$\begin{aligned}\mathbb{E}(c_{x\hat{x}}) &= \sum_{j=1}^k \sum_{i=1}^k \mathbb{P}(x=i) \mathbb{P}(\hat{x}=j) c_{ij} \\ &= \sum_{j=1}^k \sum_{i=1}^k \theta_i \hat{p}_j c_{ij} \\ &= \sum_{j=1}^k \hat{p}_j \sum_{i=1}^k \theta_i c_{ij}\end{aligned}\tag{3}$$

This is a weighted sum of all \hat{p}_j , and note that $\sum_{j=1}^k \hat{p}_j = 1$. Therefore, the optimal solution is:

$$\begin{aligned}\mathcal{A} &\stackrel{\text{def}}{=} \arg \min_j \left\{ \sum_{i=1}^k \theta_i c_{ij} \right\} \\ \forall j \in \mathcal{A}, \hat{p}_j &\geq 0 \\ \sum_{j \in \mathcal{A}} \hat{p}_j &= 1 \\ \forall j \notin \mathcal{A}, \hat{p}_j &= 0\end{aligned}\tag{4}$$

The probability can be arbitrarily distributed among all $j \in \mathcal{A}$, as long as their sum is 1. They will obtain the same minimal loss value.

The idea of proof for the solution is that, if we redistribute some probability $\Delta > 0$ to $j \notin \mathcal{A}$ (say from $j_1 \in \mathcal{A}$ to $j_2 \notin \mathcal{A}$), then the new loss

$$\begin{aligned}\mathbb{E}^{\text{new}}(c_{x\hat{x}}) &= \mathbb{E}^{\text{old}}(c_{x\hat{x}}) + \Delta \left(\sum_{i=1}^k \theta_i c_{i,j_2} - \sum_{i=1}^k \theta_i c_{i,j_1} \right) \\ &\because j_1 \in \mathcal{A}, j_2 \notin \mathcal{A} \\ \sum_{i=1}^k \theta_i c_{i,j_2} &> \sum_{i=1}^k \theta_i c_{i,j_1} \\ \therefore \mathbb{E}^{\text{new}}(c_{x\hat{x}}) &> \mathbb{E}^{\text{old}}(c_{x\hat{x}})\end{aligned}\tag{5}$$

Therefore, any change from the optimal solution will lead to a larger loss. So the optimal solution is proved to be optimal.

2 Language Identification with Naive Bayes (8 pts each)

Implement a character-based Naive Bayes classifier that classifies a document as English, Spanish, or Japanese - all written with 26 lower-case characters and space.

The dataset is languageID.tgz, unpack it. This dataset consists of 60 documents in English, Spanish, and Japanese. The correct class label is the first character of the filename: $y \in \{e, j, s\}$. (Note: here each file is a document in the corresponding language, and it is regarded as one data.)

We will be using a character-based multinomial Naïve Bayes model. You need to view each document as a bag of characters, including space. We have made sure that there are only 27 different types of printable characters (a to z, and space) – there may be additional control characters such as new-line, please ignore those. Your vocabulary will be these 27 character types. (Note: not word types!)

In the following questions, you may use the additive smoothing technique to smooth categorical data, in case the estimated probability is zero. Given N data samples $\{\mathbf{x}^{(i)}, y^{(i)}\}_{i=1}^N$, where $\mathbf{x}^{(i)} = [x_1^{(i)}, \dots, x_j^{(i)}, \dots, x_{M_i}^{(i)}]$ is a bag of characters, M_i is the total number of characters in $\mathbf{x}^{(i)}$, $x_j^{(i)} \in S, y^{(i)} \in L$ and we have $|S| = K_S, |L| = K_L$. Here S is the set of all character types, and L is the set of all classes of data labels. Then by the additive smoothing with parameter α , we can estimate the conditional probability as

$$P_\alpha(a_s | y = c_k) = \frac{(\sum_{i=1}^N \sum_{j=1}^{M_i} \mathbb{1}[x_j^{(i)} = a_s, y^{(i)} = c_k]) + \alpha}{(\sum_{b_s \in S} \sum_{i=1}^N \sum_{j=1}^{M_i} \mathbb{1}[x_j^{(i)} = b_s, y^{(i)} = c_k]) + K_S \alpha},$$

where $a_s \in S, c_k \in L$. Similarly, we can estimate the prior probability

$$P_\alpha(Y = c_k) = \frac{(\sum_{i=1}^N \mathbb{1}[y^{(i)} = c_k]) + \alpha}{N + K_L \alpha},$$

where $c_k \in L$ and N is the number of training samples.

1. Use files 0.txt to 9.txt in each language as the training data. Estimate the prior probabilities $\hat{p}(y = e)$, $\hat{p}(y = j)$, $\hat{p}(y = s)$ using additive smoothing with parameter $\frac{1}{2}$. Give the formula for additive smoothing with parameter $\frac{1}{2}$ in this case. Print the prior probabilities.

Solution: In this case, we have 10 samples in each language. Therefore,

$$\begin{aligned}\hat{p}(y = e) &= \frac{10 + \frac{1}{2}}{30 + \frac{3}{2}} = 33.33\% \\ \hat{p}(y = j) &= \frac{10 + \frac{1}{2}}{30 + \frac{3}{2}} = 33.33\% \\ \hat{p}(y = s) &= \frac{10 + \frac{1}{2}}{30 + \frac{3}{2}} = 33.33\%\end{aligned}\tag{6}$$

2. Using the same training data, estimate the class conditional probability (multinomial parameter) for English

$$\theta_{i,e} := \hat{p}(c_i \mid y = e)$$

where c_i is the i -th character. That is, $c_1 = a, \dots, c_{26} = z, c_{27} = \text{space}$. Again, use additive smoothing with parameter $\frac{1}{2}$. Give the formula for additive smoothing with parameter $\frac{1}{2}$ in this case. Print θ_e which is a vector with 27 elements.

The formula:

$$P_\alpha(a_s \mid y = e) = \frac{(\sum_{i=1}^N \sum_{j=1}^{M_i} \mathbb{1}[x_j^{(i)} = a_s, y^{(i)} = e]) + \frac{1}{2}}{(\sum_{b_s \in S} \sum_{i=1}^N \sum_{j=1}^{M_i} \mathbb{1}[x_j^{(i)} = b_s, y^{(i)} = e]) + 27 \times \frac{1}{2}}\tag{7}$$

The estimated results:

P(a|English): 6.02% P(b|English): 1.11% P(c|English): 2.15%
P(d|English): 2.20% P(e|English): 10.54% P(f|English): 1.89%
P(g|English): 1.75% P(h|English): 4.72% P(i|English): 5.54%
P(j|English): 0.14% P(k|English): 0.37% P(l|English): 2.90%
P(m|English): 2.05% P(n|English): 5.79% P(o|English): 6.45%
P(p|English): 1.68% P(q|English): 0.06% P(r|English): 5.38%
P(s|English): 6.62% P(t|English): 8.01% P(u|English): 2.67%
P(v|English): 0.93% P(w|English): 1.55% P(x|English): 0.12%
P(y|English): 1.38% P(z|English): 0.06% P(|English): 17.92%

3. Print θ_j, θ_s , the class conditional probabilities for Japanese and Spanish.

For Japanese:

P(a|Japanese): 13.18% P(b|Japanese): 1.09% P(c|Japanese): 0.55%
P(d|Japanese): 1.72% P(e|Japanese): 6.02% P(f|Japanese): 0.39%
P(g|Japanese): 1.40% P(h|Japanese): 3.18% P(i|Japanese): 9.70%

$P(j|\text{Japanese}): 0.23\%$ $P(k|\text{Japanese}): 5.74\%$ $P(l|\text{Japanese}): 0.14\%$
 $P(m|\text{Japanese}): 3.98\%$ $P(n|\text{Japanese}): 5.67\%$ $P(o|\text{Japanese}): 9.12\%$
 $P(p|\text{Japanese}): 0.09\%$ $P(q|\text{Japanese}): 0.01\%$ $P(r|\text{Japanese}): 4.28\%$
 $P(s|\text{Japanese}): 4.22\%$ $P(t|\text{Japanese}): 5.70\%$ $P(u|\text{Japanese}): 7.06\%$
 $P(v|\text{Japanese}): 0.02\%$ $P(w|\text{Japanese}): 1.97\%$ $P(x|\text{Japanese}): 0.00\%$
 $P(y|\text{Japanese}): 1.42\%$ $P(z|\text{Japanese}): 0.77\%$ $P(\text{ }|\text{Japanese}): 12.34\%$

For Spanish:

$P(a|\text{Spanish}): 10.46\%$ $P(b|\text{Spanish}): 0.82\%$ $P(c|\text{Spanish}): 3.75\%$
 $P(d|\text{Spanish}): 3.97\%$ $P(e|\text{Spanish}): 11.38\%$ $P(f|\text{Spanish}): 0.86\%$
 $P(g|\text{Spanish}): 0.72\%$ $P(h|\text{Spanish}): 0.45\%$ $P(i|\text{Spanish}): 4.99\%$
 $P(j|\text{Spanish}): 0.66\%$ $P(k|\text{Spanish}): 0.03\%$ $P(l|\text{Spanish}): 5.29\%$
 $P(m|\text{Spanish}): 2.58\%$ $P(n|\text{Spanish}): 5.42\%$ $P(o|\text{Spanish}): 7.25\%$
 $P(p|\text{Spanish}): 2.43\%$ $P(q|\text{Spanish}): 0.77\%$ $P(r|\text{Spanish}): 5.93\%$
 $P(s|\text{Spanish}): 6.58\%$ $P(t|\text{Spanish}): 3.56\%$ $P(u|\text{Spanish}): 3.37\%$
 $P(v|\text{Spanish}): 0.59\%$ $P(w|\text{Spanish}): 0.01\%$ $P(x|\text{Spanish}): 0.25\%$
 $P(y|\text{Spanish}): 0.79\%$ $P(z|\text{Spanish}): 0.27\%$ $P(\text{ }|\text{Spanish}): 16.83\%$

4. Treat e10.txt as a test document x . Represent x as a bag-of-words count vector (Hint: the vocabulary has size 27). Print the bag-of-words vector x .

Results:

$'a': 164, 'b': 32, 'c': 53, 'd': 57, 'e': 311, 'f': 55, 'g': 51, 'h': 140, 'i': 140, 'j': 3, 'k': 6, 'l': 85,$
 $'m': 64, 'n': 139, 'o': 182, 'p': 53, 'q': 3, 'r': 141, 's': 186, 't': 225, 'u': 65, 'v': 31, 'w': 47, 'x':$
 $4, 'y': 38, 'z': 2, ' ': 498$

5. For the x of e10.txt, compute $\hat{p}(x | y)$ for $y = e, j, s$ under the multinomial model assumption, respectively. Use the formula

$$\hat{p}(x | y) = \prod_{i=1}^d (\theta_{i,y})^{x_i}$$

where $x = (x_1, \dots, x_d)$. Show the three values: $\hat{p}(x | y = e), \hat{p}(x | y = j), \hat{p}(x | y = s)$.

Hint: you may notice that we omitted the multinomial coefficient. This is ok for classification because it is a constant w.r.t. y . Also, Store all probabilities here and below in $\log()$ internally to avoid underflow. This also means you need to do arithmetic in log space.

Results:

Language e log prob: -7841.865447060635
 Language j log prob: -8771.433079075032
 Language s log prob: -8467.282044010557

That means

$$\begin{aligned}
 \hat{p}(x | y = e) &= e^{-7842} \\
 \hat{p}(x | y = j) &= e^{-8771} \\
 \hat{p}(x | y = s) &= e^{-8467}
 \end{aligned} \tag{8}$$

6. For the x of e10.txt, use the Bayes rule and your estimated prior and likelihood, compute the posterior $\hat{p}(y | x)$. Show the three values: $\hat{p}(y = e | x)$, $\hat{p}(y = j | x)$, $\hat{p}(y = s | x)$. Show the predicted class label of x .

Solution:

$$\begin{aligned}
 \hat{p}(y = c_k | x) &= \frac{\hat{p}(x | y = c_k) \hat{p}(y = c_k)}{\hat{p}(x)} \\
 \hat{p}(x) &= \sum_{c_k \in \{e, j, s\}} \hat{p}(x | y = c_k) \hat{p}(y = c_k) \\
 \therefore \hat{p}(y = c_k) &= \frac{1}{3}, \forall c_k = e, j, s \\
 \therefore \hat{p}(y = c_k | x) &= \frac{\hat{p}(x | y = c_k)}{\sum_{c_k \in \{e, j, s\}} \hat{p}(x | y = c_k)} \\
 \therefore \hat{p}(y = e | x) &= 1 \\
 \hat{p}(y = j | x) &= 0 \\
 \hat{p}(y = s | x) &= 0
 \end{aligned} \tag{9}$$

7. Evaluate the performance of your classifier on the test set (files 10.txt to 19.txt in three languages). Present the performance using a confusion matrix. A confusion matrix summarizes the types of errors your classifier makes, as shown in the table below. The columns are the true language a document is in, and the rows are the classified outcome of that document. The cells are the number of test documents in that situation. For example, the cell with row = English and column = Spanish contains the number of test documents that are really Spanish but misclassified as English by your classifier.

	English	Spanish	Japanese
English	10	0	0
Spanish	0	10	0
Japanese	0	0	10

8. Take a test document. Arbitrarily shuffle the order of its characters so that the words (and spaces) are scrambled beyond human recognition. How does this shuffling affect your Naive Bayes classifier's prediction on this document? Explain the key mathematical step in the Naive Bayes model that justifies your answer.

I take the English 10 document and shuffle it. The results are still:

Language e log prob: -7841.865447060635

Language j log prob: -8771.433079075032

Language s log prob: -8467.282044010557

And the predicted class is still English. That's because the classifier only cares about the number of each character in a document, and doesn't consider the order of the characters.

3 Simple Feed-Forward Network (20pts)

In this exercise, you will derive, implement back-propagation for a simple neural network and compare your output with some standard library's output. Consider the following 3-layer neural network.

$$\hat{y} = f(x) = g(W_3 \sigma(W_2 \sigma(W_1 x)))$$

Suppose $x \in \mathbb{R}^d$, $W_1 \in \mathbb{R}^{d_1 \times d}$, $W_2 \in \mathbb{R}^{d_2 \times d_1}$, $W_3 \in \mathbb{R}^{k \times d_2}$ i.e. $f: \mathbb{R}^d \rightarrow \mathbb{R}^k$. Let $\sigma(z) = [\sigma(z_1), \dots, \sigma(z_n)]$ for any $z \in \mathbb{R}^n$ where $\sigma(z) = \frac{1}{1+e^{-z}}$ is the sigmoid (logistic) activation function and $g(z_i) = \frac{\exp(z_i)}{\sum_{i=1}^k \exp(z_i)}$

is the softmax function. Suppose the true pair is (x, y) where $y \in \{0, 1\}^k$ with exactly one of the entries equal to 1, and you are working with the cross-entropy loss function given below,

$$L(x, y) = - \sum_{i=1}^k y \log(\hat{y}_i)$$

1. Derive backpropagation updates for the above neural network. (5 pts)

Solution: Denote $W_3\sigma(W_2\sigma(W_1x))$ as $Z^{(3)}$, denote $W_2\sigma(W_1x)$ as $Z^{(2)}$, and W_1x as $Z^{(1)}$.

$$\begin{aligned} \frac{dL(x, y)}{d \log \hat{y}_j} &= -y_j \\ \because \log \hat{y}_j &= z_j - \log \sum_{i=1}^k \exp(z_i) \\ \therefore \frac{d \log \hat{y}_i}{dZ_j^{(3)}} &= \begin{cases} 1 - g(Z_j^{(3)}), & i = j \\ -g(Z_j^{(3)}), & i \neq j \end{cases} \\ \therefore \frac{dL}{dZ_j^{(3)}} &= - \sum_{i=1}^k y_i \frac{d \log \hat{y}_i}{dZ_j^{(3)}} = \begin{cases} -y_i(1 - \hat{y}_i) = \hat{y}_j - y_j, & i = j (y_j = 1) \\ \hat{y}_j = \hat{y}_j - y_j, & i \neq j (y_j = 0) \end{cases} \\ &= \hat{y}_j - y_j \\ \therefore \frac{dL}{dZ^{(3)}} &= \hat{y} - y \\ \frac{dL}{dW_3} &= \frac{dL}{dZ^{(3)}} \frac{dZ^{(3)}}{dW_3} = (\hat{y} - y)\sigma(Z^{(2)}) \\ \frac{dL}{dZ^{(2)}} &= \frac{dL}{dZ^{(3)}} \frac{dZ^{(3)}}{dZ^{(2)}} = (\hat{y} - y)W_3\sigma(Z^{(2)})(1 - \sigma(Z^{(2)})) \\ \frac{dL}{dW_2} &= \frac{dL}{dZ^{(2)}} \frac{dZ^{(2)}}{dW_2} = (\hat{y} - y)W_3\sigma(Z^{(2)})(1 - \sigma(Z^{(2)}))\sigma(Z^{(1)}) \\ \frac{dL}{dZ^{(1)}} &= \frac{dL}{dZ^{(2)}} \frac{dZ^{(2)}}{dZ^{(1)}} = (\hat{y} - y)W_3\sigma(Z^{(2)})(1 - \sigma(Z^{(2)}))W_2\sigma(Z^{(1)})(1 - \sigma(Z^{(1)})) \\ \frac{dL}{dW_1} &= \frac{dL}{dZ^{(1)}} \frac{dZ^{(1)}}{dW_1} = (\hat{y} - y)W_3\sigma(Z^{(2)})(1 - \sigma(Z^{(2)}))W_2\sigma(Z^{(1)})(1 - \sigma(Z^{(1)}))x \end{aligned} \tag{10}$$

2. Implement it in NumPy or PyTorch using basic linear algebra operations. (e.g. You are not allowed to use auto-grad, built-in optimizer, model, etc. in this step. You can use library functions for data loading, processing, etc.). Evaluate your implementation on MNIST dataset, report test errors and learning curve. (10 pts)

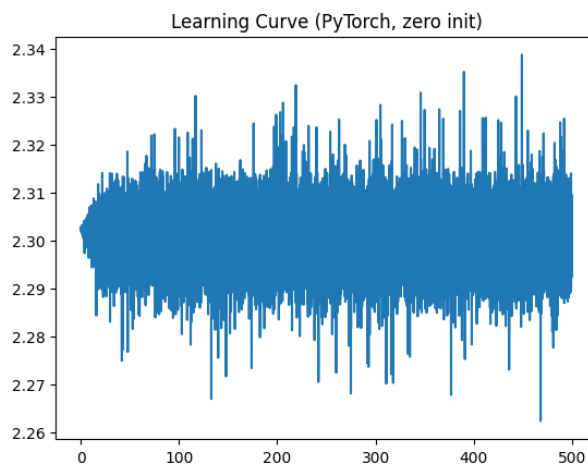

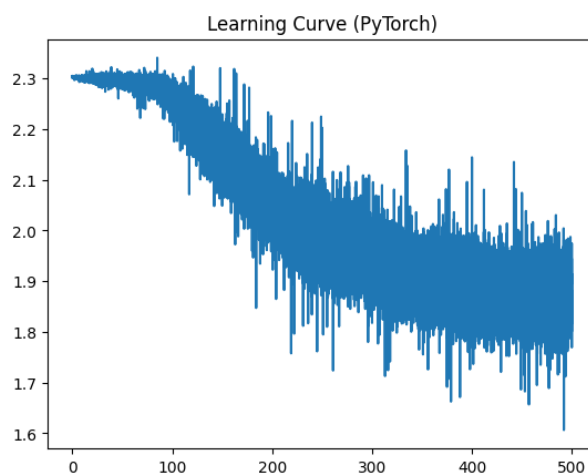

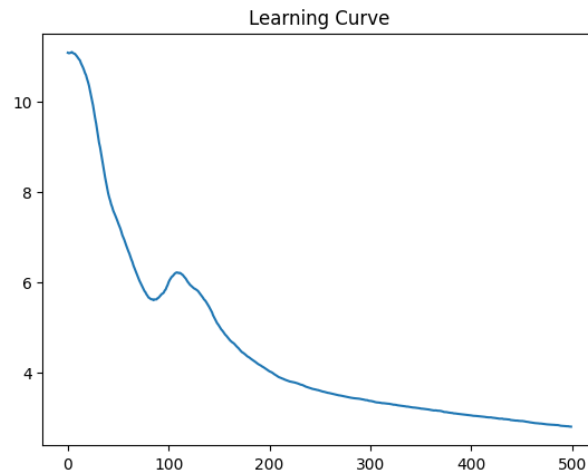

Solution: Due to time limit, I used only 10000 samples for training, and 10000 different samples for testing. Also, I only let the training last 500 time epochs. My batch size for training is 128. The learning curve: The error rate for test set is 68.03%.

3. Implement the same network in PyTorch (or any other framework). You can use all the features of the framework e.g. auto-grad etc. Evaluate it on MNIST dataset, report test errors, and learning curve. (2 pts)

Solution: I'm using the same setting as the by hand version. The error rate for test set is 41.57%.

4. Try different weight initialization a) all weights initialized to 0, and b) initialize the weights randomly between -1 and 1. Report test error and learning curves for both. (You can use either of the implementations) (3 pts)

Solution: In the implementation by hand, I'm using a random initial weights from $\mathcal{N}(0, 1)$. In the PyTorch implementation, I'm using the 'kaiming uniform' initialization of weights, which is also randomly distributed and centered around 0. In this question, I'll show the results using PyTorch, with all weights initialized as 0. The error rate for test set is 88.65%.

You should play with different hyperparameters like learning rate, batch size, etc. for your own learning. You only need to report results for any particular setting of hyperparameters. You should mention the values of those along with the results. Use $d_1 = 300$, $d_2 = 200$, $d_3 = 100$. For optimization use SGD (Stochastic gradient descent) without momentum, with some batch size say 32, 64, etc. MNIST can be obtained from here (<https://pytorch.org/vision/stable/datasets.html>)
